- 6. XYZ coordinates for the configurations in Fig. 3**

1. Theoretical methodology and construction of the quaternary Pd-Ag-C-H G-NN potential

1.1 Architecture of neural network potential

Scheme S1. Scheme of the HDNN architecture. The subscripts $(1, i, \dots, N)$ are atom indices and represent the total atoms in a structure. The inputs of NN are a set of structural descriptors $\{G\}$, which are constructed from the Cartesian coordinates $\{R\}$ of the structure, while the outputs of NN are the atomic properties $\{E_i, F_i, S_i\}$, i.e., energies, forces, and stresses. The overall properties, E^{tot} , F^{tot} , and S^{tot} , can be calculated from the individual atomic contributions.

In this work, we utilized the high dimensional neural network (HDNN) scheme to construct the global NN (G-NN) potential, as shown in Scheme S1. The input nodes to NN are a set of structural descriptors of a structure, as detailedly discussed in our previous works.¹⁻³ The total energy E^{tot} of the structure can be composed as a linear combination of its atomic energy E^i from the output of NN

$$E^{tot} = \sum_i E^i \quad (1)$$

Consistently, the atomic force can be analytically derived from the total energy, i.e., the force component $F_{k,\alpha}$ ($\alpha = x, y$, or z) acting on atom k is the derivative of the total energy E^{tot} with respect to coordinate $R_{k,\alpha}$. In combination with Eq. 1, the force component $F_{k,\alpha}$ then is related to the derivatives of the atomic energy E^i with respect to the j^{th} structural descriptors of atom i , $G_{j,i}$

$$F_{k,\alpha} = -\frac{\partial E^{tot}}{\partial R_{k,\alpha}} = -\sum_{i,j} \frac{\partial E^i}{\partial G_{j,i}} \frac{\partial G_{j,i}}{\partial R_{k,\alpha}} \quad (2)$$

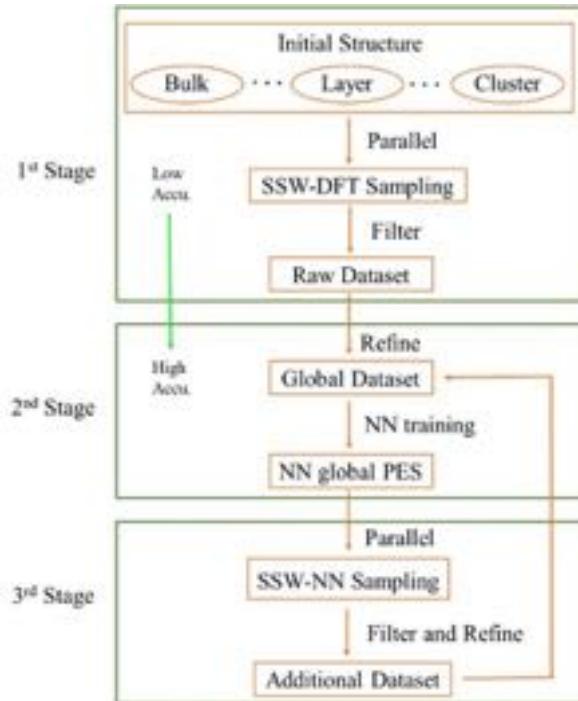

Similarly, the element $\sigma_{\alpha\beta}$ of static stress tensor matrix can be analytically derived as

$$\sigma_{\alpha\beta} = -\frac{1}{V} \sum_{i,j,d} \frac{(r_d)_\alpha (r_d)_\beta}{r_d} \frac{\partial E^i}{\partial G_{j,i}} \frac{\partial G_{j,i}}{\partial r_d} \quad (3)$$

where r_d and r_d are the distance vector, constituted by $G_{j,i}$ and its module, respectively, and V is the volume of the structure.

1.2 Generation of global dataset using SSW-NN

Undoubtedly, the quality of the potential energy surface (PES) of G-NN is largely determined by its training dataset. Here we utilized the stochastic surface walking (SSW) global optimization⁴⁻⁶ to generate a global dataset, which is fully automated and does not need a priori knowledge on the system, such as the structural motif, e.g. bonding patterns and symmetry. The final obtained Pd-Ag-C-H global dataset contains a variety of structural patterns on the global PES, as summarized in Table S1.

Scheme S2. Procedure for the generation of the global training dataset by SSW global optimization. In the first stage, the SSW sampling is typically performed by low accuracy DFT calculations. In the second stage, the global dataset is first refined with high accuracy DFT setups, and then a NN training is performed based on the accurate global dataset. In the third stage, an additional dataset is generated by SSW sampling utilizing the previously obtained NN PES, and is fed into the global dataset. A new cycle of NN training then starts based on the new global dataset (back to stage 2).

In brief, the SSW-NN method involves three stages to generate the global dataset (see Scheme S2), as described below.

(i) **The first stage** generates a raw dataset, which contains the most common atomic environment and serves to build an initial NN PES. This is done by performing density functional theory (DFT) SSW global optimization in a massively parallel way. In this stage, the DFT calculations have low accuracy setups and small unit cells to speed up the SSW search. By collecting and screening the structures from SSW trajectories, a raw dataset is obtained.

(ii) **The second stage** trains a NN global PES. This is done by refining the dataset using DFT calculations with high accuracy setups, followed by NN training on the accurate global dataset (see our previous work⁷ for details). The NN architecture applied in this stage utilizes a small set of structural descriptors and a small network size.

(iii) **The third stage** iteratively expands the global dataset. It targets to increase the predictive power of NN PES by incorporating more structural patterns into the dataset. This is done by performing SSW PES search using the NN PES obtained in the second stage, starting from a variety of initial structures. These initial structures are randomly constructed, and also include large systems with many atoms per unit cell. The structures from all the SSW trajectories are collected and filtered to generate an additional dataset. The new dataset is then fed to the global dataset to start a new cycle of NN training (back to stage 2).

Table S1. Structural information of the global PES dataset for G-NN potential training. The listed data is the number of structures in the dataset, as distinguished by chemical formula, the number of atoms per cell (N_{atm}), and the type of the structure, including cluster (N_{cls}), layer (N_{lay}), and bulk (N_{bul}). The total number of the structures (N_{tot}) is also summarized.

Chem. Formula	N_{atm}	N_{cls}	N_{lay}	N_{bul}	N_{tot}

1.3 Benchmark of G-NN potential against DFT calculations

To examine the accuracy of the G-NN potential, we have calculated the total energy difference between G-NN and DFT for the representative surface structures of Pd-Ag-H/Pd₁Ag₃(111), Pd-Ag-H/Pd₁Ag₃(100), Pd-Ag-H/Pd₁Ag₁(111), and Pd-Ag-H/Pd₁Ag₁(100), which shows a low root mean square error (RMSE) of only 4.9 meV/atom, as seen in Figure S1.

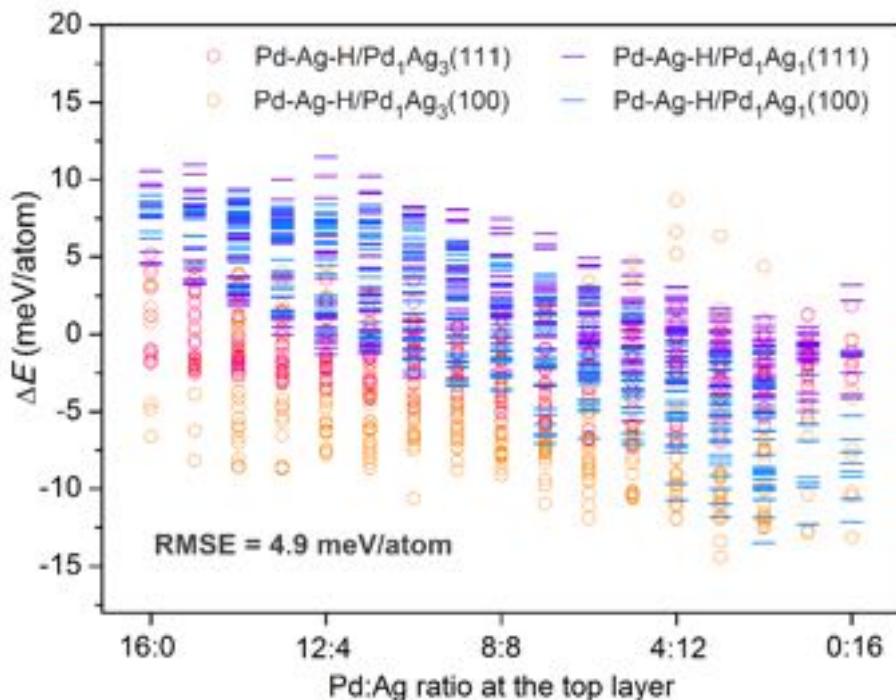

Figure S1. Total energy difference between G-NN potential and DFT calculations for the representative surface structures of Pd-Ag-H/Pd₁Ag₃(111), Pd-Ag-H/Pd₁Ag₃(100), Pd-Ag-H/Pd₁Ag₁(111), and Pd-Ag-H/Pd₁Ag₁(100), as distinguished by the Pd/Ag ratio at the top layer. The H coverage does not reflect in the figure.

One great advantage of the G-NN potential is the predictive power to chemical reactions, i.e., the PES near the transition states. For example, we have calculated the acetylene/ethene hydrogenation energetics (including the transition states and intermediate states) on $\text{Pd}_1\text{Ag}_3/\text{Pd}_1\text{Ag}_3(111)$ by using G-NN and DFT (see Table S2), which show small energy differences (< 3 meV/atom) illustrating the high accuracy of G-NN for the hydrogenation reactions.

Table S2. Comparison of the energetics for acetylene/ethene hydrogenation on $\text{Pd}_1\text{Ag}_3/\text{Pd}_1\text{Ag}_3(111)$ from G-NN and DFT single point calculation.

2. Surface structures of Pd₁Ag₁

In the main text, we have revealed the Pd-Ag-H surface PES for Pd₁Ag₃(111) and Pd₁Ag₃(100) (see Figure 2), where Pd₁Ag₃(111) has a set of energy-nearly-degenerate surface structures while Pd₁Ag₃(100) has only the mostly Ag-covered surfaces. Here we briefly discuss the surface PES for Pd₁Ag₁(111) and Pd₁Ag₁(100). As shown in Figure S2, both Pd₁Ag₁(111) and Pd₁Ag₁(100) have the major Pd exposure on surface, and therefore the most stable configurations, Pd/Pd₁Ag₁(111)-1 ML H and Pd₃Ag₁/Pd₁Ag₁(100)-1 ML H, both have the H coverage up to 1 ML with respect to the surface metal atom.

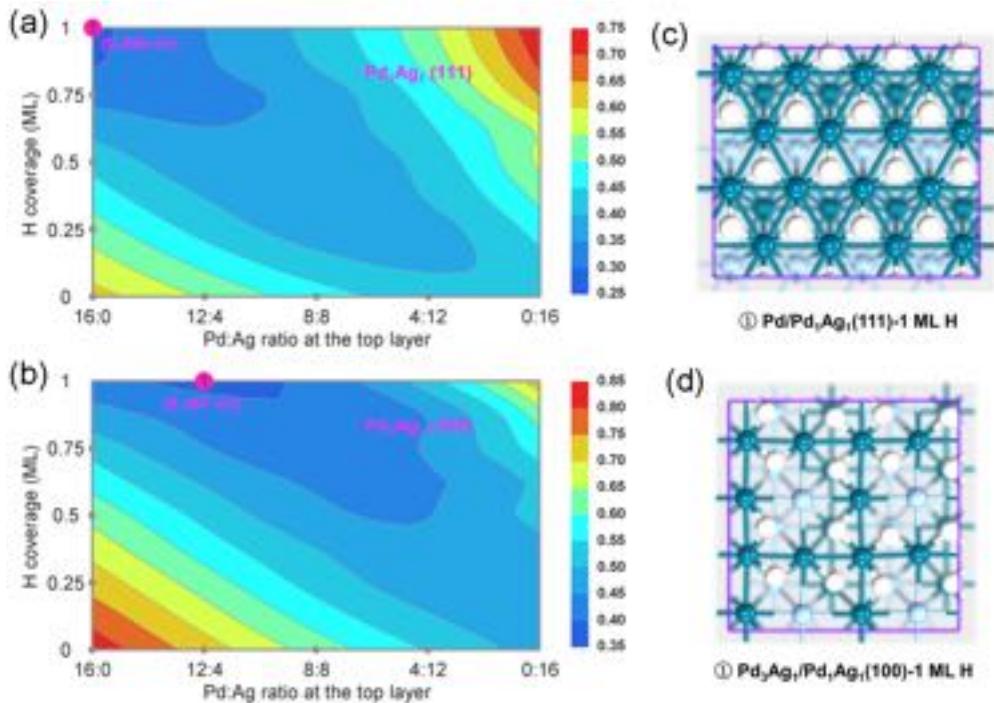

Figure S2. (a-b) DFT contour maps for the formation free energy of Pd-Ag-H/Pd₁Ag₁(111) and Pd-Ag-H/Pd₁Ag₁(100), at 25 °C, $p(\text{H}_2) = 0.05$ atm. The formation free energy here is averaged to each metal atom at the top layer. (c-d) Stable surface configurations of Pd₁Ag₁(111) and Pd₁Ag₁(100) at typical reaction conditions, as determined from the Pd-Ag-H surface contour maps.

3. Kinetic parameters utilized in microkinetic simulation

Table S3. Gibbs free energy barrier for the acetylene/ethene hydrogenation on Pd₁Ag₃/Pd₁Ag₃(111), Pd/Pd₁Ag₃(111), Pd₁Ag₇/Pd₁Ag₃(100), Pd/Pd₁Ag₁(111), and Pd₃Ag₁/Pd₁Ag₁(100). The data is with respect to the experiment reaction conditions, i.e. 60 °C, and 1 bar for all the gas phase molecules (e.g. hydrogen, acetylene, ethene, and ethane) since the effect of pressure change has been explicitly taken into account in the microkinetic simulation via standard thermodynamic equation.

4. Synthesis and characterization of Pd-Ag catalysts

4.1 Materials

Palladium nitrate hydrate ($\text{Pd}(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$, 40% Pd basis) and Hydrotalcite (HT, $\text{Mg}_6\text{Al}_2(\text{CO}_3)(\text{OH})_{16} \cdot 4\text{H}_2\text{O}$) were obtained from Sigma-Aldrich. Silver nitrate (AgNO_3 , 63.5%), green silicon carbide (SiC, 99.0%, an average particle size of 60 mesh), quartz wool, $\alpha\text{-Al}_2\text{O}_3$, $\gamma\text{-Al}_2\text{O}_3$, SiO_2 , Y_2O_3 , CaCO_3 , rutile- TiO_2 (r- TiO_2), anatase- TiO_2 (a- TiO_2), P25, and Ti-MWW were purchased from Sinopharm Chemical Reagent Co.. Nitrogen (N_2 , 99.99%), hydrogen (5% H_2 and 95% Ar), helium (He, 99.99%), and the mixed gas (0.5% C_2H_2 , 50.0% C_2H_4 , 5.0% H_2 , 4.0% He and 40.5% N_2) were supplied by Shanghai Air Liquide Co., Ltd. All the chemicals were used directly without further purification and the deionized water with a resistivity of 18.2 $\text{M}\Omega\cdot\text{cm}$ was used in all the experiments.

The catalyst synthesis procedure has been introduced in method section in the main text.

4.2 Instruments for catalyst characterization

The transmission electron microscopy (TEM) images were taken by Tecnai G2 F20 S-Twin (FEI, USA); the powered X-ray diffraction (XRD) patterns were obtained by Bruker D8 Advance (Cu $\text{K}\alpha$ radiation, Bruker AXS, Germany); the Pd and Ag contents of the samples were analysed by inductively coupled plasma optical emission spectrometer (ICP-AES, iCAP7400, USA);

4.3 Catalyst characterization

To examine the hydrogenation activity and selectivity on Pd-Ag alloys, we have synthesized a series of HT supported Pd-Ag nanoparticle catalysts with different Pd/Ag ratios, including Pd, Pd_1Ag_1 , Pd_1Ag_2 , Pd_1Ag_3 , Pd_1Ag_4 , and Pd_1Ag_5 , and have characterized them by XRD, TEM, and EDS-mapping, which show that: the Pd-Ag nanoparticles are uniformly dispersed on the HT support with an average particle size of $4.1 \sim 7.6$ nm (see the TEM images in Figure S4); the ICP content analysis of Pd and Ag is consistent with the nominal loading, confirming the formation of Pd-Ag alloys (see Figure S5 and Table S4); importantly, new Pd-Ag crystal phases are found at Pd_1Ag_1 and Pd_1Ag_3 as indicated by the new peaks at 39.6° and 39.1° from the XRD, in line with our theoretical convex hull diagram (see Figure 1a).

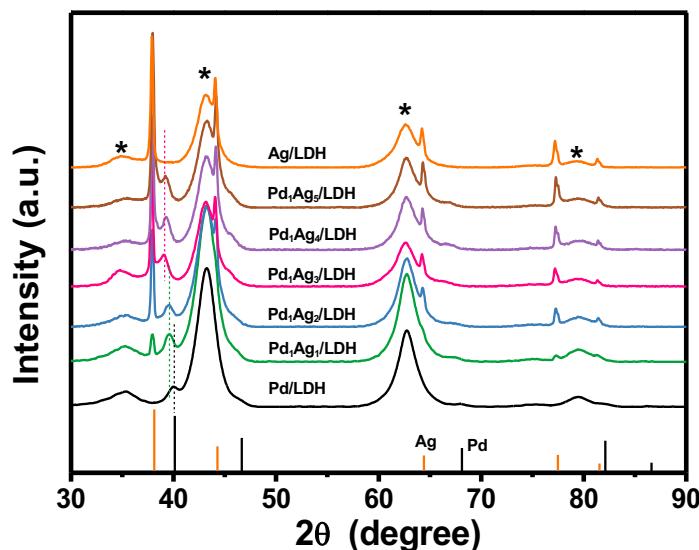

Figure S3. XRD of the Pd/HT, Pd_1Ag_1 /HT, Pd_1Ag_2 /HT, Pd_1Ag_3 /HT, Pd_1Ag_4 /HT, Pd_1Ag_5 /HT, and Ag/HT catalysts. The reference peaks are Pd (JCPDS 46-1043) and Ag (JCPDS 04-0783), while the background peaks from the HT support are denoted by asterisks.

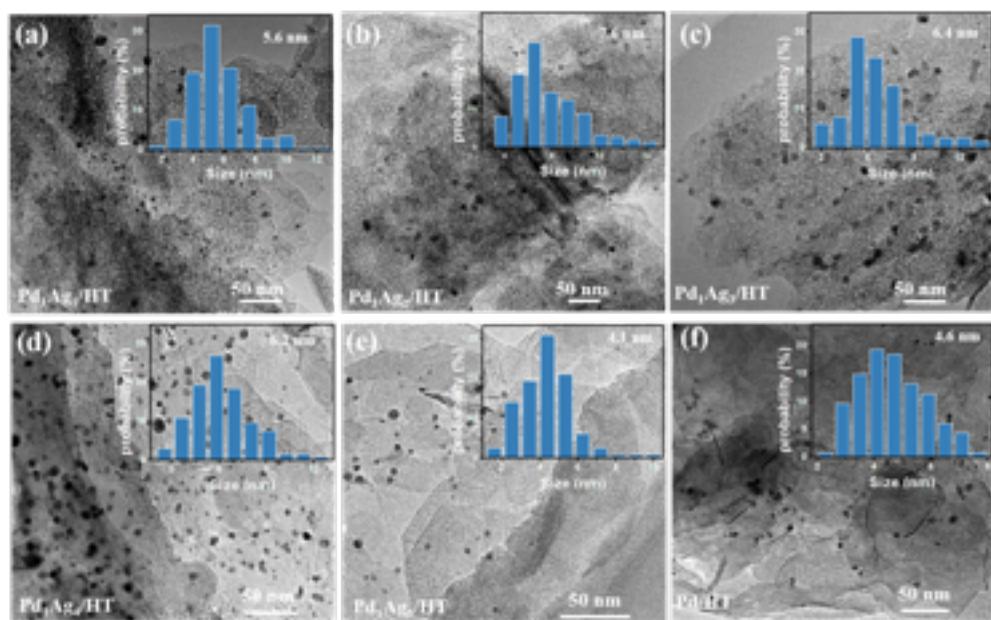

Figure S4. TEM and statistics of the nanoparticle size for (a) $\text{Pd}_1\text{Ag}_1/\text{HT}$, (b) $\text{Pd}_1\text{Ag}_2/\text{HT}$, (c) $\text{Pd}_1\text{Ag}_3/\text{HT}$, (d) $\text{Pd}_1\text{Ag}_4/\text{HT}$, (e) $\text{Pd}_1\text{Ag}_5/\text{HT}$, and (f) Pd/HT .

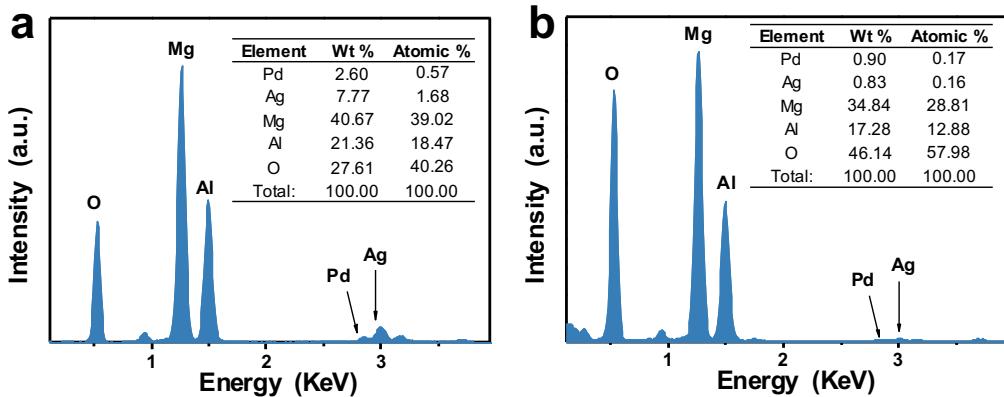

Figure S5. EDS patterns of (a) Pd₁Ag₃/HT and (b) Pd₁Ag₁/HT. The insets show the weight and atomic ratios for Pd and Ag.

Table S4. Content analysis of Pd and Ag for the Pd/HT, Pd₁Ag₁/HT, Pd₁Ag₂/HT, Pd₁Ag₃/HT, Pd₁Ag₄/HT, Pd₁Ag₅/HT, and Ag/HT catalysts.

Catalyst	Nominal loading		Actual loading ^a		Ag:Pd	Particle size (nm)
	Pd (wt%)	Ag (wt%)	Pd (wt%)	Ag (wt%)		
Pd/HT	1	-	0.93	-	-	4.6
Pd ₁ Ag ₁ /HT	1	1	0.98	1.01	1.0	5.6
Pd ₁ Ag ₂ /HT	1	2	0.89	1.91	2.1	7.6
Pd ₁ Ag ₃ /HT	1	3	0.86	2.82	3.3	6.4
Pd ₁ Ag ₄ /HT	1	4	1	3.94	3.9	6.2
Pd ₁ Ag ₅ /HT	1	5	1.08	5.74	5.3	4.3
Ag/HT	-	3	-	2.95	-	5.0

^aDetermined by ICP analysis.

We have performed a 200-hour catalysis test on the Pd₁Ag₃/HT catalyst, during which the activity gradually reduces but the selectivity remains (see Figure 4e). To reveal the structural evolution, we have analyzed the catalyst after the long-time test by HR-TEM and EDS elemental mapping (see Figure S6), which show nearly no change in particle size and no detectable deposition of carbon on the catalyst. This rules out the sintering of the nanoparticles and the formation of high-carbon weight overlayers that block the catalyst sites. With the help of microkinetic simulation, we deduce that the Pd atoms may slowly accumulate onto the surface layer forming the Pd₃ and Pd layer ensemble, which have high ethene hydrogenation barriers and thus reduce the activity.

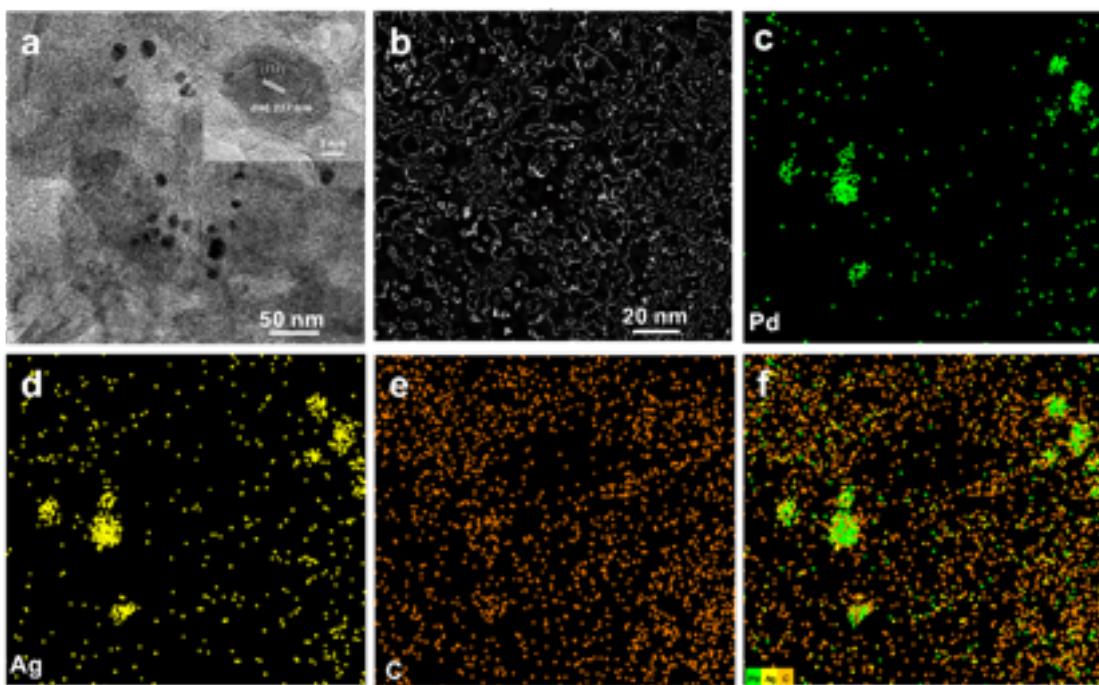

Figure S6. (a) TEM, HR-TEM (the inset) images and (b-f) the EDS elemental mapping images of the Pd₁Ag₃/HT catalyst, as taken after the 200-hour catalysis test.

Based on the atomic level understanding, we have performed the catalyst screening on the support material and the Pd₁Ag₃/TiO₂ rutile is found to have the best catalytic performance (conversion >96%, selectivity >85%, see Figure 6). We then analyzed the Pd₁Ag₃/TiO₂ rutile catalyst and found that there is no obvious peak for fcc crystal from XRD (see Figure S8), and the large Pd-Ag crystalline particles are scarce compared to that on HT support, with the average nanoparticle size below 4.9 nm as shown by TEM and HR-TEM (see Figure S7). These indicates that the rutile support can finely disperse the Pd₁Ag₃ nanoparticles and thus improve the selectivity.

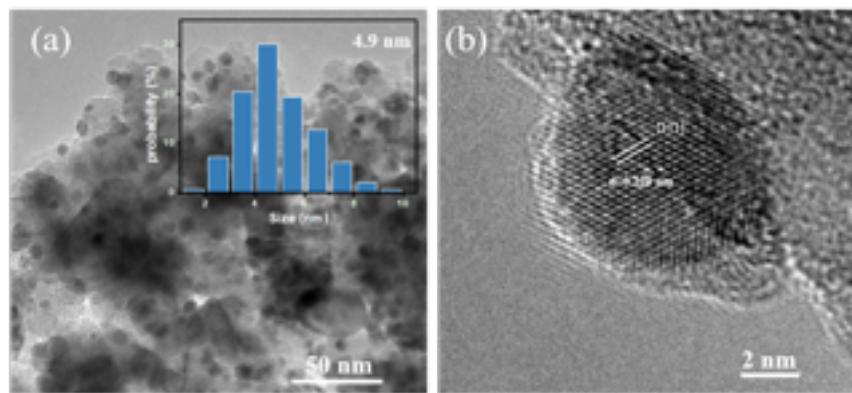

Figure S7. (a) TEM (the inset is the statistics of nanoparticle size) and (b) HR-TEM images of the Pd₁Ag₃/r-TiO₂ catalyst.

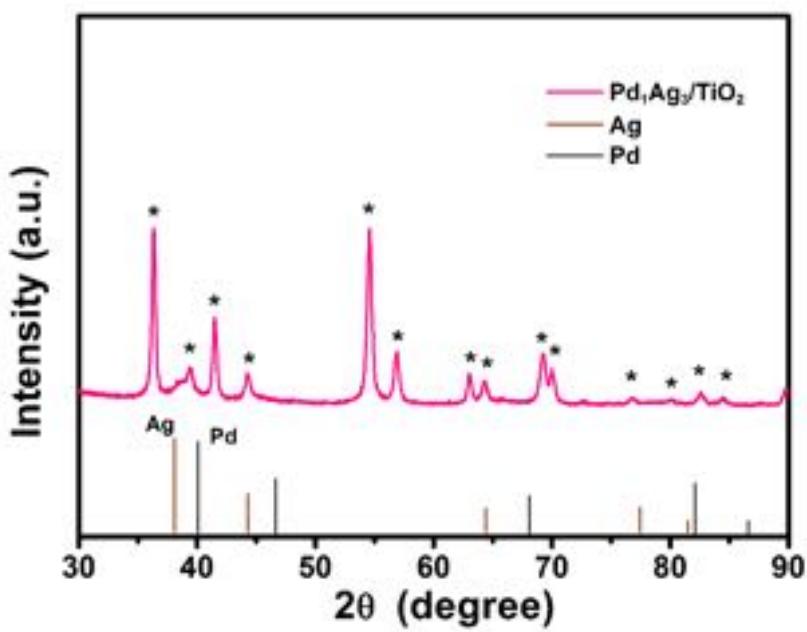

Figure S8. XRD of $\text{Pd}_1\text{Ag}_3/\text{r}-\text{TiO}_2$. The reference peaks are Pd (JCPDS 46-1043) and Ag (JCPDS 04-0783), while the background peaks from the rutile TiO_2 support are denoted by asterisks.

5. Acetylene hydrogenation catalysts reported in literatures

Table S5. Comparison of our Pd₁Ag₃/r-TiO₂ and Pd₁Ag₃/HT with the best acetylene hydrogenation catalysts reported previously.
